Vaccinated vs. Unvaccinated—Part 7

The cumulative data from this 2004 survey strongly suggests that unvaccinated children are far healthier than their vaccinated peers by nearly every metric.

By Robert F. Kennedy, Jr., Chairman, Children's Health Defense

To date, I have posted 41 slides from 41 studies in this series comparing health outcomes among vaccinated populations vs unvaccinated populations. These four new slides (total now 45) illustrate data from The Netherlands Survey, a 2004 study of 635 Dutch children compiled from questionnaires filled out by their parents.

The Netherlands survey was completed and paid for by the Nederlandse Vereniging Kritisch Prikken, an independent association of Dutch therapists, doctors and parents, and others. The cumulative data from all these studies strongly suggests that unvaccinated children are far healthier than their vaccinated peers by nearly every metric. Thanks Dr Brian Hooker for rendering the graphs.

Slides and Summaries from Part 7:

Slide 1 and Summary:

In episodes of various illnesses per 100 children over the first five years of life, ear infections, throat inflammation, aggressive behavior, and convulsions were all markedly elevated in fully vaccinated children compared to unvaccinated peers.

Netherlands Fully Vaccinated Versus Unvaccinated Study, 2004

The NVKP (Nederlandse Vereniging Kritisch Prikken) [in English: Dutch Association for Conscientious Vaccination] is an independent association made up of therapists, doctors and parents, amongst others. The NVKP's aim is freedom of choice for parents when it comes to vaccinating their children, based on honest, comprehensive and independent information. We view the current 'one size fits all' vaccination policy with great concern. The NVKP is therefore urging the adoption of more thorough independent research by representatives from different disciplines.

The survey:

The NVKP survey was conducted in the Netherlands in the latter half of 2004 with the parents of 635 children, and involved both members and non-members of the NVKP. The survey was geographically distributed over the entire country, and the postal codes of the respondents are known. We asked the parents to fill in a questionnaire with questions about the health of their child or children. All parents were subsequently approached for supplementary information and were asked to answer control questions. The personal details of all the participating parents and children are known. Questionnaires that were not filled out properly or questionnaires from parents who did not react to our request for supplementary information and/or control questions were not included in the results.

Questionnaires from the parents of children that were not vaccinated in the normal way – that is, not entirely in accordance with Dutch Vaccination Programme (RVP) – and questionnaires from the parents of children that were not entirely unvaccinated were also excluded from this survey.

Episodes of Various Illnesses Per 100 Children Over the First 5 Years of Life

“The NVKP survey was conducted in the Netherlands in the latter half of 2004 with the parents of 635 children, and involved both members and non-members of the NVKP.”

Slide 2 and Summary:

In episodes of various illnesses per 100 children over the first five years of life, antibiotic use, fever, febrile convulsions, and hospital admissions were all markedly elevated in fully vaccinated children compared to unvaccinated peers.

“The NVKP survey was conducted in the Netherlands in the latter half of 2004 with the parents of 635 children, and involved both members and non-members of the NVKP.”

Slide 3 and Summary:

In the episodes of various illnesses per 100 children over the first five years of life, the number of children who were described as “sickly”, those who had chronic eczema, and those with asthma or chronic lung disease was markedly higher among vaccinated children compared to unvaccinated peers.
